All points randomly generated from a  $\chi^2_5$  distribution.

# Are there any anomalies?

Old Faithful eruptions from 14 January 2017 to 29 December 2023

# Definitions of anomalies

## Definition: Anomaly

Given a set of observations  $\{y_1, \dots, y_n\}$  and a generalized probability density  $f$ , the **anomaly score** of  $y_i$  wrt  $f$  is

$$p_i = \mathbb{P}(f(Y) \leq f(y_i))$$

where  $Y$  has density  $f$ . An observation is an **anomaly** wrt  $f$  if  $p_i < \alpha$  for some threshold  $\alpha > 0$ .

# Definitions of anomalies

## Definition: Anomaly

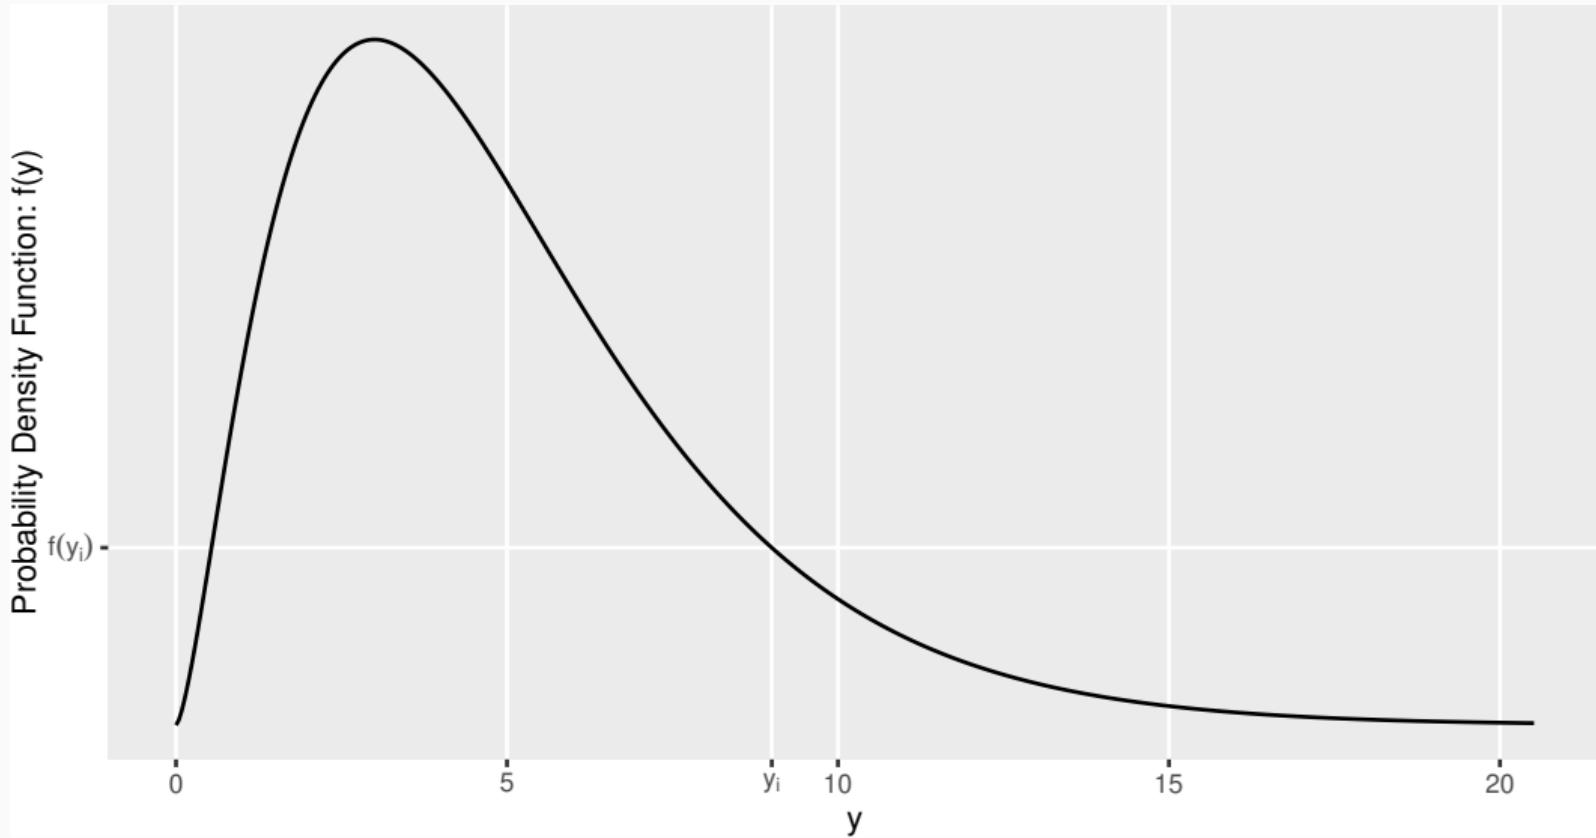

Given a set of observations  $\{y_1, \dots, y_n\}$  and a generalized probability density  $f$ , the **anomaly score** of  $y_i$  wrt  $f$  is

$$p_i = \mathbb{P}(f(Y) \leq f(y_i))$$

where  $Y$  has density  $f$ . An observation is an **anomaly** wrt  $f$  if  $p_i < \alpha$  for some threshold  $\alpha > 0$ .

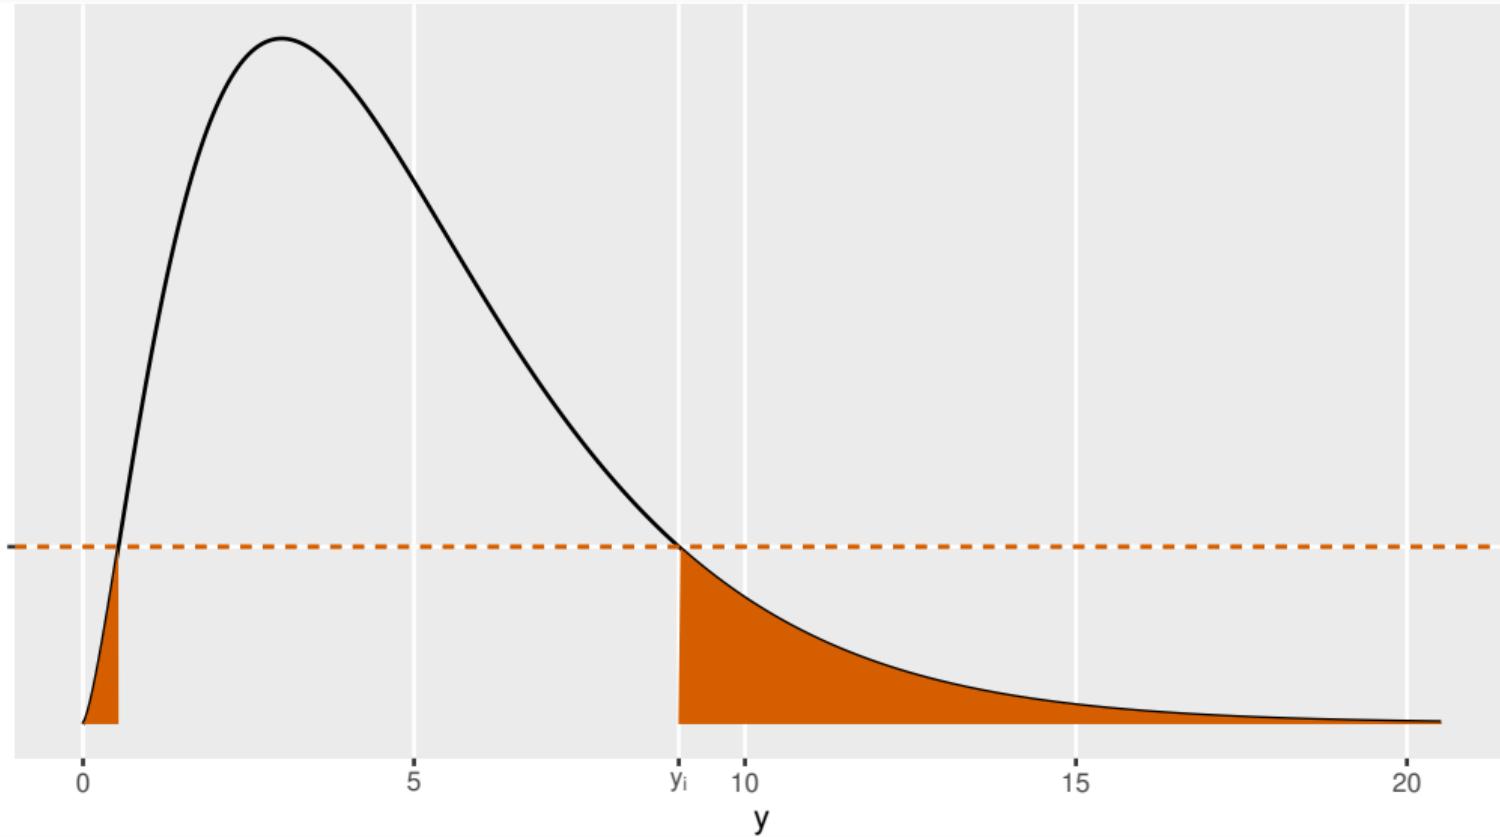

- $y_i$  can be a scalar, vector or a more complex object
- $f$  can be a conditional density, and can be known, assumed or estimated

# Definitions of anomalies

# Definitions of anomalies

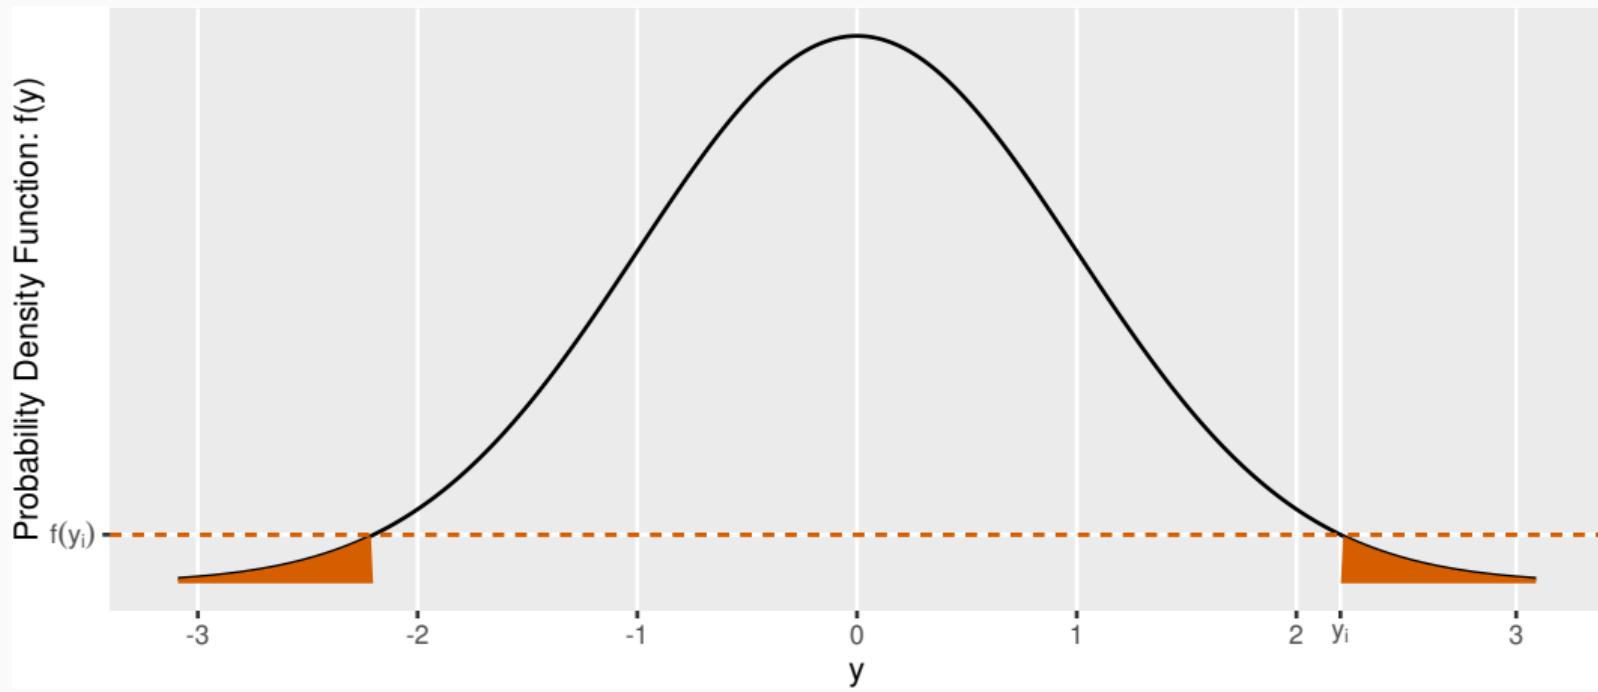

Probability Density Function:  $f(y)$

# Anomaly detection: Normal distribution

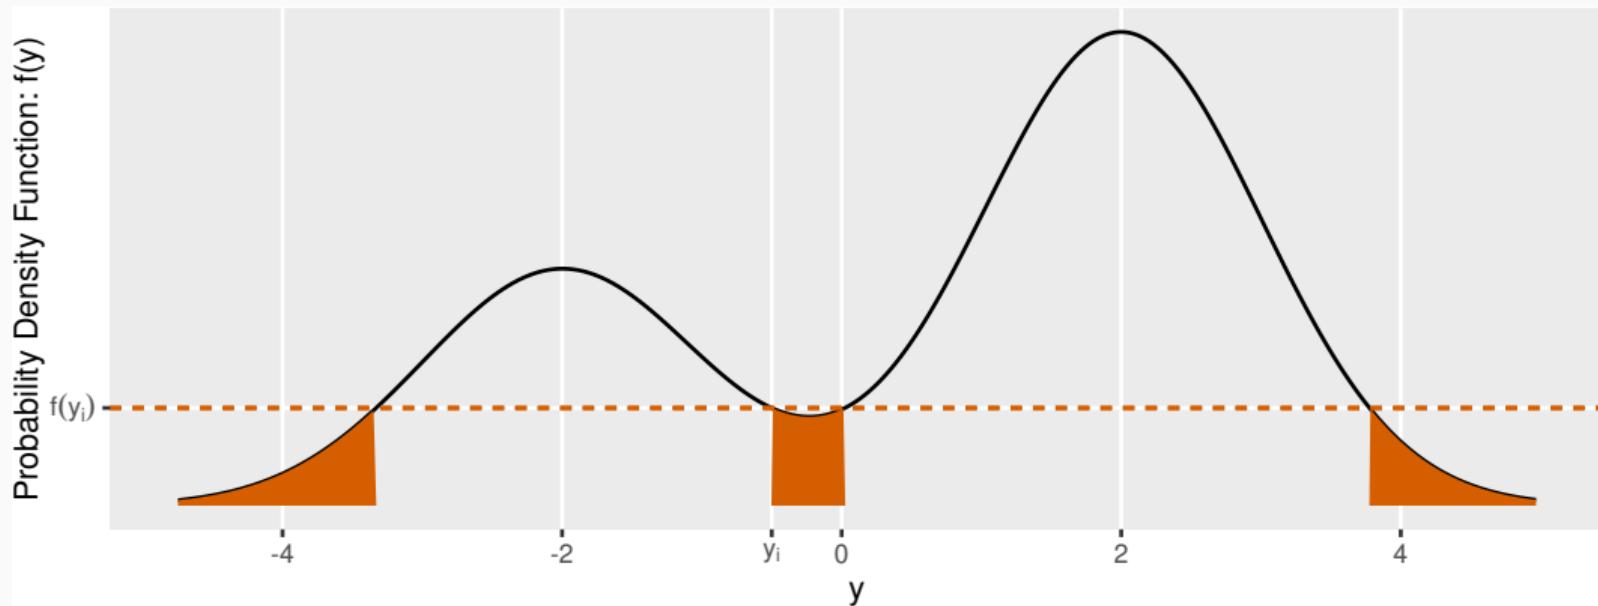

If  $f \sim N(\mu, \sigma^2)$ , then  $p_i = 2 [1 - \Phi(|y_i - \mu|/\sigma)]$

Equivalent to a two-sided p-value from a z-score test.

# Anomaly detection: Highest density regions

HDR with probability  $1 - \alpha$  is  $R_\alpha = \{y : f(y) \geq c_\alpha\}$  where  $c_\alpha$  is largest constant s.t.  $\mathbb{P}(Y \in R_\alpha) \geq 1 - \alpha$ .  
An observation is an anomaly if  $y_i \notin R_\alpha$ .

# Surprises

## Definition: Surprisal

The **surprisal** of an observation  $y_i$  drawn from a probability distribution with density  $f$  is defined as

$$s_i = -\log f(y_i)$$

- Better known as “log scores” in statistics.
- “Surprisal” coined by Tribus (1961).
- Expected surprisal = entropy of random variable
- Sum of surprisals = negative log likelihood

# Anomaly detection using surprisals

Let  $G(s) = \mathbb{P}(S \leq s)$  be the **surprisal distribution** where  $S = -\log f(Y)$  and  $Y$  has density  $f$ .

$$G(s) = \mathbb{P}(-\log f(Y) \leq s) = \mathbb{P}(f(Y) \geq e^{-s})$$

Then  $p_i = 1 - G(s_i)$ .

# Anomaly detection using surprisals

Let  $G(s) = \mathbb{P}(S \leq s)$  be the **surprisal distribution** where  $S = -\log f(Y)$  and  $Y$  has density  $f$ .

$$G(s) = \mathbb{P}(-\log f(Y) \leq s) = \mathbb{P}(f(Y) \geq e^{-s})$$

Then  $p_i = 1 - G(s_i)$ .

- An anomaly is an extreme value of the surprisal distribution.
- It is not necessarily extreme in the sample space of  $f$ .

# Fisher-Tippett-Gnedenko theorem

Consider  $n$  iid rvs  $S_1, \dots, S_n$  with cdf  $G$  and  $M_n = \max\{S_1, \dots, S_n\}$ . If there exist sequences of constants  $\{a_n > 0\}$  and  $\{b_n\}$  such that

$$\mathbb{P}\left\{(M_n - b_n)/a_n \leq z\right\} \rightarrow H(z) \quad \text{as } n \rightarrow \infty,$$

for a non-degenerate cdf  $H$ , then

$$H(z) = \exp\left\{-\left[1 + \xi\left(\frac{z - \mu}{\sigma}\right)\right]^{-1/\xi}\right\}$$

- $\xi < 0$ : Weibull distribution ( $G$  bounded upper tail)
- $\xi \rightarrow 0$ : Gumbel distribution ( $G$  light-tailed)
- $\xi > 0$ : Fréchet distribution ( $G$  heavy-tailed)

## Pickands-Balkema-De Haan theorem

If  $G$  satisfies the FTG theorem, then the upper tail of  $G$  can be approximated by the Generalized Pareto Distribution (GPD):

$$\mathbb{P}(S \leq u + s \mid S > u) = 1 - \left(1 + \frac{\xi s}{\sigma_u}\right)^{-1/\xi}$$

for large enough  $u$ , where  $\sigma_u = \sigma + \xi(u - \mu)$ .

## Pickands-Balkema-De Haan theorem

If  $G$  satisfies the FTG theorem, then the upper tail of  $G$  can be approximated by the Generalized Pareto Distribution (GPD):

$$\mathbb{P}(S \leq u + s \mid S > u) = 1 - \left(1 + \frac{\xi s}{\sigma_u}\right)^{-1/\xi}$$

for large enough  $u$ , where  $\sigma_u = \sigma + \xi(u - \mu)$ .

So in practice, we can approximate the upper tail of many distributions by a GPD.

# Surprises and EVT

- Suppose we have  $n$  iid observations  $Y_1, \dots, Y_n$  and a density  $f$ .
- Let  $S_i = -\log f(Y_i)$  be the surprisal of  $Y_i$  wrt  $f$
- Then  $S_1, \dots, S_n$  are iid from the surprisal distribution  $G(s) = \mathbb{P}(S \leq s)$ .
- If  $G$  satisfies the FTG theorem, then we can approximate the upper tail of  $G$  by a GPD fitted to the top  $1 - \beta$  of the surprisal values.
- In practice, we typically use  $\beta = 0.9$ .

# Three-type theorem for surprises

**A1: Sub-Gaussian:**  $S = -\log f(Y)$  satisfies, for all  $\lambda \in \mathbb{R}$ , and some  $\nu > 0$ ,  $\mathbb{E} \exp\{\lambda(S - \mathbb{E}[S])\} \leq \exp\{\lambda^2 \nu^2 / 2\}$ .

**A2: Sub-exponential:**  $S$  is sub-exponential with parameters  $\nu$  and  $b$ , i.e.,  $\mathbb{E} \exp\{\lambda(S - \mathbb{E}[S])\} \leq \exp\{\lambda^2 \nu^2 / 2\}$  for all  $|\lambda| < 1/b$ .

**A3: Polynomial:**  $|S|$  has polynomial moments of order  $p \geq 1$ ; i.e.,  $\mathbb{E}[|S|^p] \leq C^p$  for some  $C > 0$  such that  $C^p - 1 > 0$ .

- A1 satisfied when  $f$  has bounded support
- A2 satisfied when  $\log f$  unbounded below, and light tails (e.g., Gaussian)
- A3 satisfied when  $f$  has heavy tails (e.g., t with df  $\geq 3$ )

# Three-type theorem for surprisals

Let  $y_1, \dots, y_n$  be an iid sequence from density  $f$ ,  $s_i = -\log f(y_i)$ ,  $M_n = \max\{s_1, \dots, s_n\}$ , and  $S = -\log f(Y)$  where  $Y \sim f$ .

1 Under A1:

$$\sup_{s:s>0} \left| \mathbb{P} \left\{ |M_n - \mathbb{E}[S]| \geq \sqrt{2\nu^2 s} + \sqrt{2\nu^2 \log(2n)} \right\} - e^{-s} \right| = o(1).$$

2 Under A2:

$$\sup_{s:s>1/b} \left| \mathbb{P} \left\{ |M_n - \mathbb{E}[S]| \geq (2b)s + (2b)\log(2n) \right\} - e^{-e^{-s}} \right| = o(1).$$

3 Under A3:

$$\sup_{s:s>c} \left| \mathbb{P} \left\{ |M_n - \mathbb{E}[S]| \geq (Csn^{1/p}) \right\} - e^{-s^{-p}} \right| = o(1).$$

# Three-type theorem for surprisals

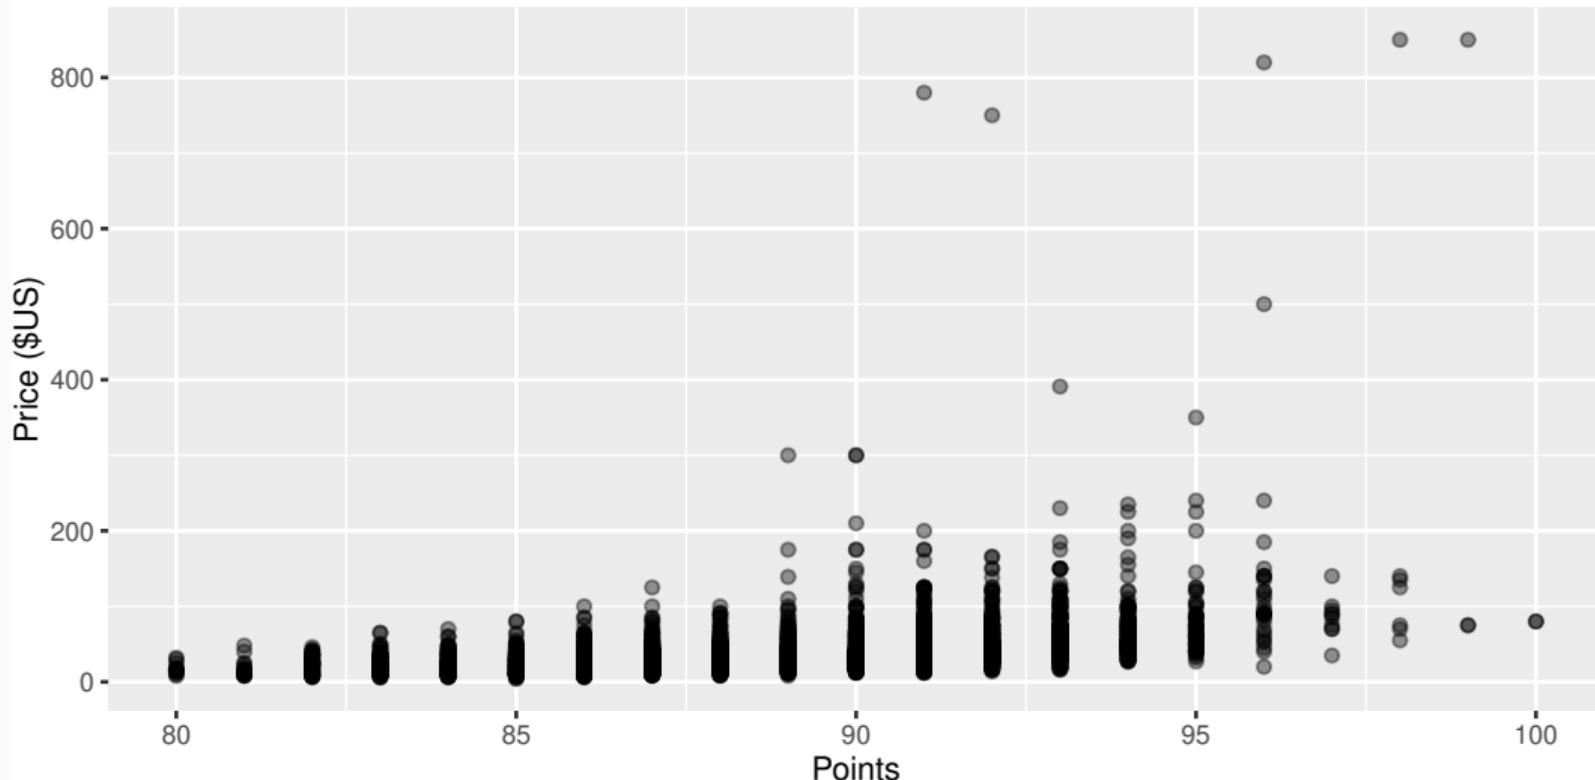

- If surprisal has Gaussian like tails, then maximum surprisal is a reversed Weibull;
- If surprisal only has an exponential tail, then maximum surprisal is Gumbel;
- If surprisal only has a polynomial moment, then maximum surprisal is Fréchet.

## Corollary

upper tail of the surprisal distribution can be approximated by a GPD, even if the assumed density  $f$  is incorrect, provided one of A1–A3 is satisfied.

# Outline

1 Anomalies

2 Surprises

3 Extreme value theory and surprises

4 Lookout algorithm

5 Conclusions

# Lookout algorithm

- Compute Kernel Density Estimate (KDE) of the observations, with a bandwidth matrix chosen using persistent homology.
- Compute surprisals from KDE values
- Fit a Generalized Pareto Distribution (GPD) to the largest  $1 - \beta$  surprisals
- Compute surprisal probabilities  $p_i$  from the fitted GPD.
- An observation is an anomaly if  $p_i < \alpha$ .

# Kernel density estimation

Observations:  $\mathbf{y}_i \in \mathbb{R}^m$  for  $i \in \{1, \dots, n\}$ .

## KDE

$$\hat{f}(\mathbf{y}) = \frac{1}{n} \sum_{i=1}^n |\mathbf{H}|^{-1/2} K(\mathbf{H}^{-1/2}(\mathbf{y} - \mathbf{y}_i)),$$

- $K$  is a square-integrable spherically-symmetric function, bounded below by 0, with a finite second-order moment and unit integral.
- $\mathbf{H}$  is a symmetric  $m \times m$  positive-definite matrix.

# Kernel density estimation

Observations:  $\mathbf{y}_i \in \mathbb{R}^m$  for  $i \in \{1, \dots, n\}$ .

## KDE

$$\hat{f}(\mathbf{y}) = \frac{1}{n} \sum_{i=1}^n |\mathbf{H}|^{-1/2} K(\mathbf{H}^{-1/2}(\mathbf{y} - \mathbf{y}_i)),$$

- $K$  is a square-integrable spherically-symmetric function, bounded below by 0, with a finite second-order moment and unit integral.
- $\mathbf{H}$  is a symmetric  $m \times m$  positive-definite matrix.

## LOO KDE values

$$f_{-i} = \frac{1}{n-1} (n\hat{f}(\mathbf{y}_i) - \mathbf{H}^{-1/2}K(\mathbf{0}))$$

# Kernel density estimation

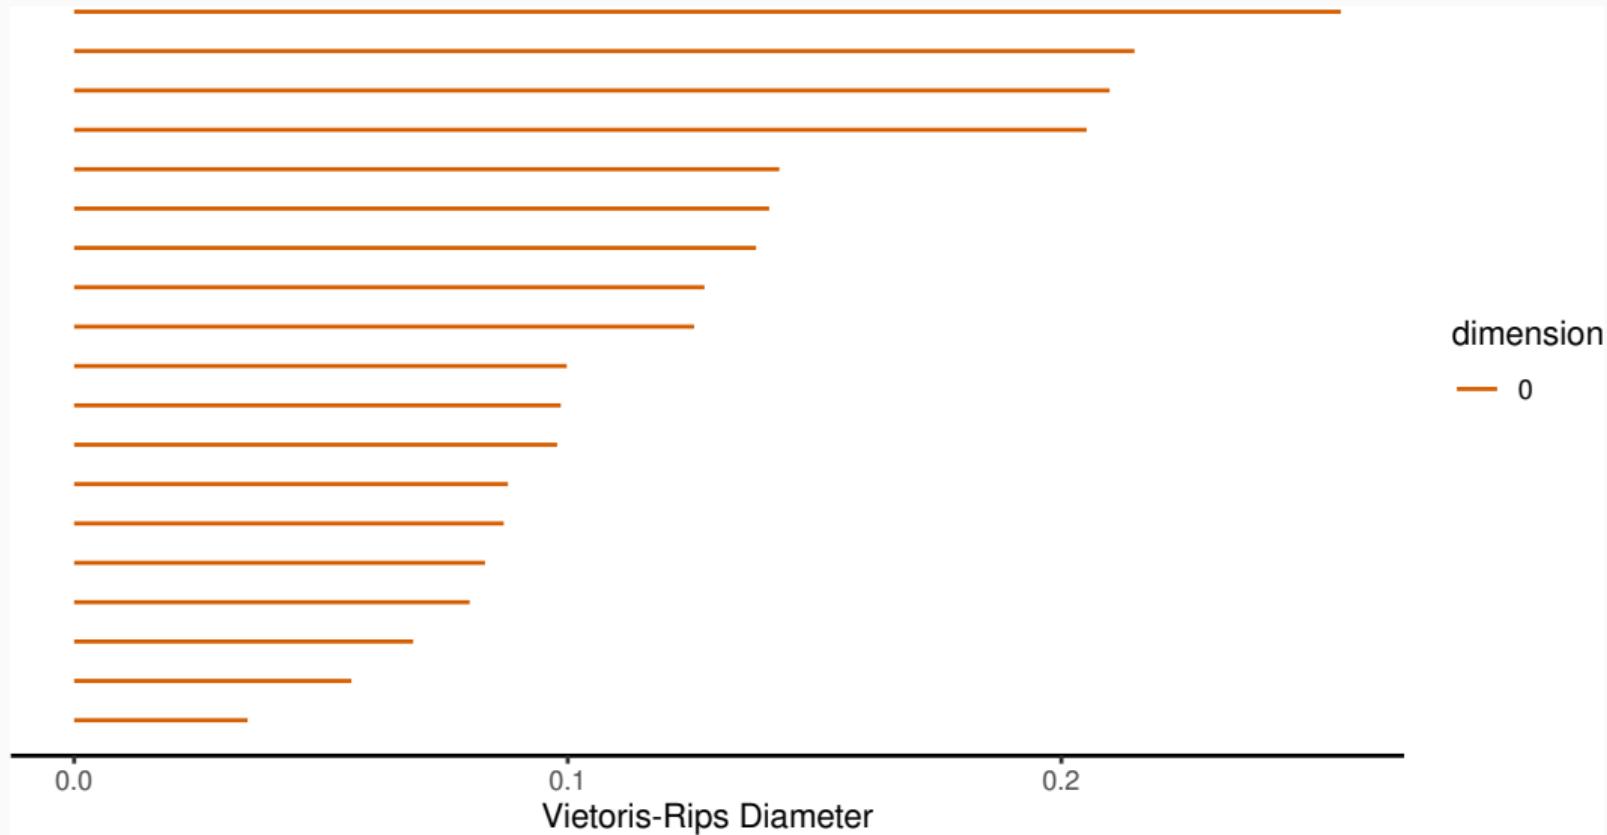

$$\hat{f}(\mathbf{y}) = \frac{1}{n} \sum_{i=1}^n |\mathbf{H}|^{-1/2} K(\mathbf{H}^{-1/2}(\mathbf{y} - \mathbf{y}_i))$$

## GPD fitted to KDE surprisals

- Compute surprisals from KDE values:  $s_i = -\log f_i$ ,  $i = 1, \dots, n$ .
- $f_i$  are bounded above and below, so the surprisals are sub-Gaussian.
- Fit GPD to largest  $1 - \beta$  of  $\{s_i\}_{i=1}^n$ , constraining shape parameter to be non-positive.

# Persistent homology

# Persistent homology

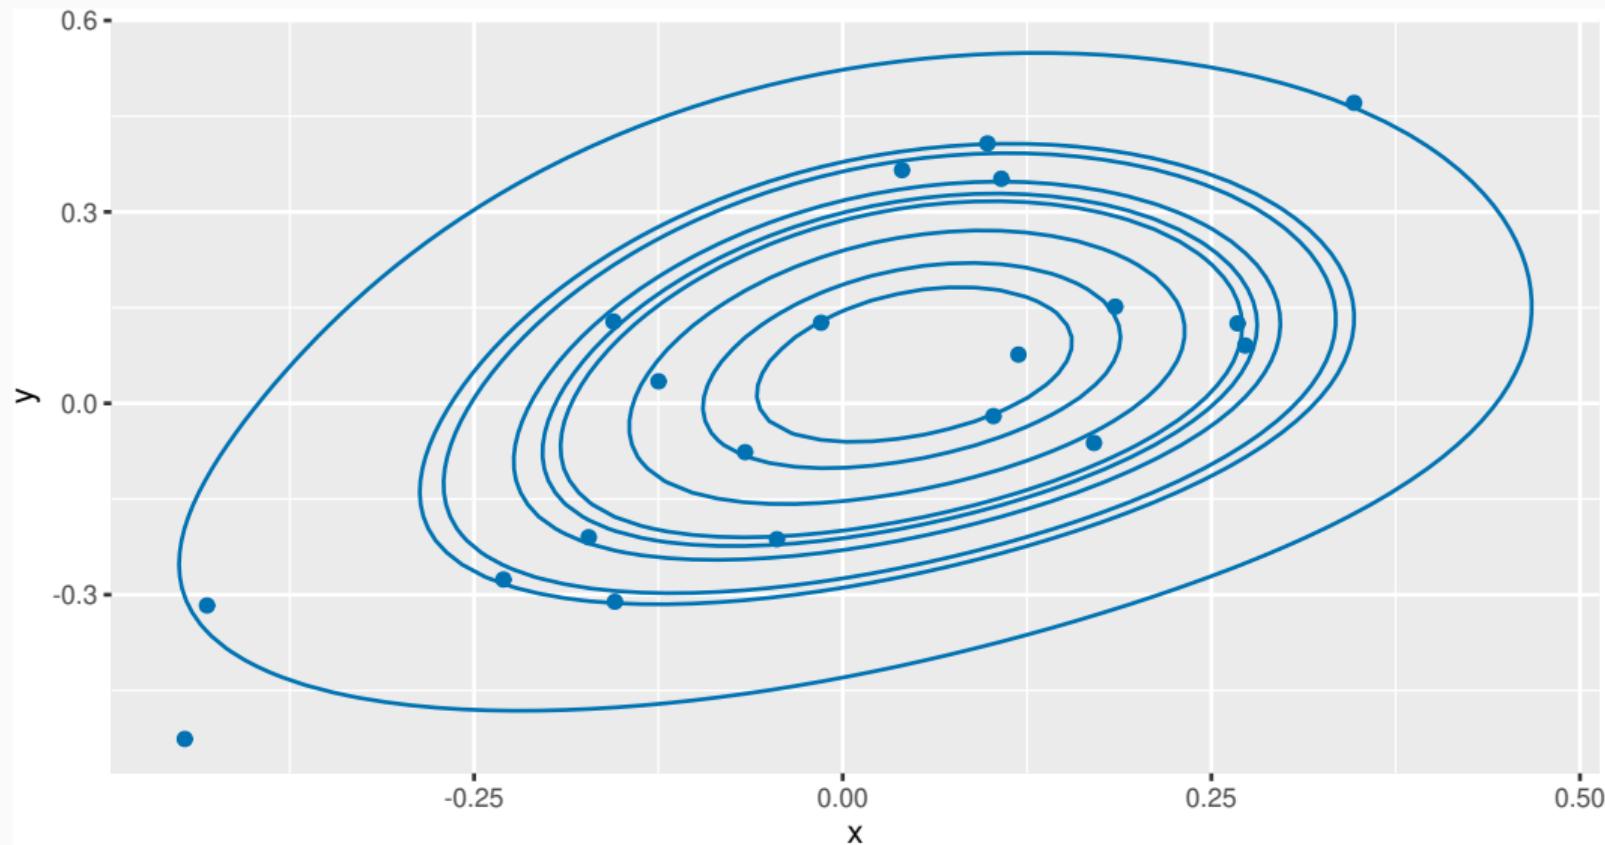

# KDE bandwidth selection via VR diameters

- 1 Compute persistence homology barcode of data for dimension 0 using Vietoris-Rips diameter.
- 2 Obtain ordered death diameters  $\{d_i\}_{i=1}^n$ .
- 3 Let  $d_\gamma^* = \gamma$  sample quantile computed from  $\{d_i\}_{i=1}^n$ , for some large  $\gamma < 1$
- 4 Set bandwidth matrix  $H = (d_\gamma^*)^{2/m} I_m$ .

- Assumes each dimension has the same scale.
- Ensures that persistently connected components have large weights in the KDE at each observed point.
- In practice, we use  $\gamma = 0.97$ .

# KDE bandwidth selection via VR diameters

# Kernel density estimation (consistency)

Let  $Y_1, \dots, Y_n$  be iid from square integrable density function  $f$ . Then KDE is a *consistent* estimator of  $f$  if

$$\lim_{n \rightarrow 0} E \left[ \left( \hat{f}(\mathbf{u}) - f(\mathbf{u}) \right)^2 d\mathbf{u} \right] = 0$$

For  $\hat{f}$  to be a consistent estimator,  $\mathbf{H}$  must be a symmetric positive-definite matrix that satisfies the following conditions:

- All elements of  $\mathbf{H}$  approach zero as  $n \rightarrow \infty$
- $n^{-1}|\mathbf{H}|^{-1/2} \rightarrow 0$  as  $n \rightarrow \infty$

# KDE bandwidth selection via VR diameters

## Theorem

Let  $f : \mathbb{R}^m \rightarrow \mathbb{R}$  be a Lipschitz density function. For any  $\gamma \in (0, 1)$ ,  $d_{\gamma}^* \rightarrow 0$  a.s., where  $d_{\gamma}^* = \gamma$  quantile of finite death times.

# KDE bandwidth selection via VR diameters

## Theorem

Let  $f : \mathbb{R}^m \rightarrow \mathbb{R}$  be a Lipschitz density function. For any  $\gamma \in (0, 1)$ ,  $d_\gamma^* \rightarrow 0$  a.s., where  $d_\gamma^* = \gamma$  quantile of finite death times.

## Theorem

Let  $d_k = k$ th smallest death time of 0-homology for Rips filtrations of  $n$  points from distribution over  $\mathbb{R}^2$  s.t. density bounded above.

Choose any sequence of integers  $\{\omega(n)\}$  s.t.  $0 < \omega(n) < n \forall n$  and  $\lim_{n \rightarrow \infty} \omega_n = \infty$ . Then  $nd_{\omega(n)} \rightarrow \infty$  as  $n \rightarrow \infty$ .

# KDE bandwidth selection via VR diameters

## Theorem

Let  $f : \mathbb{R}^m \rightarrow \mathbb{R}$  be a Lipschitz density function. For any  $\gamma \in (0, 1)$ ,  $d_\gamma^* \rightarrow 0$  a.s., where  $d_\gamma^* = \gamma$  quantile of finite death times.

## Theorem

Let  $d_k = k$ th smallest death time of 0-homology for Rips filtrations of  $n$  points from distribution over  $\mathbb{R}^2$  s.t. density bounded above.

Choose any sequence of integers  $\{\omega(n)\}$  s.t.  $0 < \omega(n) < n \forall n$  and  $\lim_{n \rightarrow \infty} \omega_n = \infty$ . Then  $nd_{\omega(n)} \rightarrow \infty$  as  $n \rightarrow \infty$ .

## Theorem

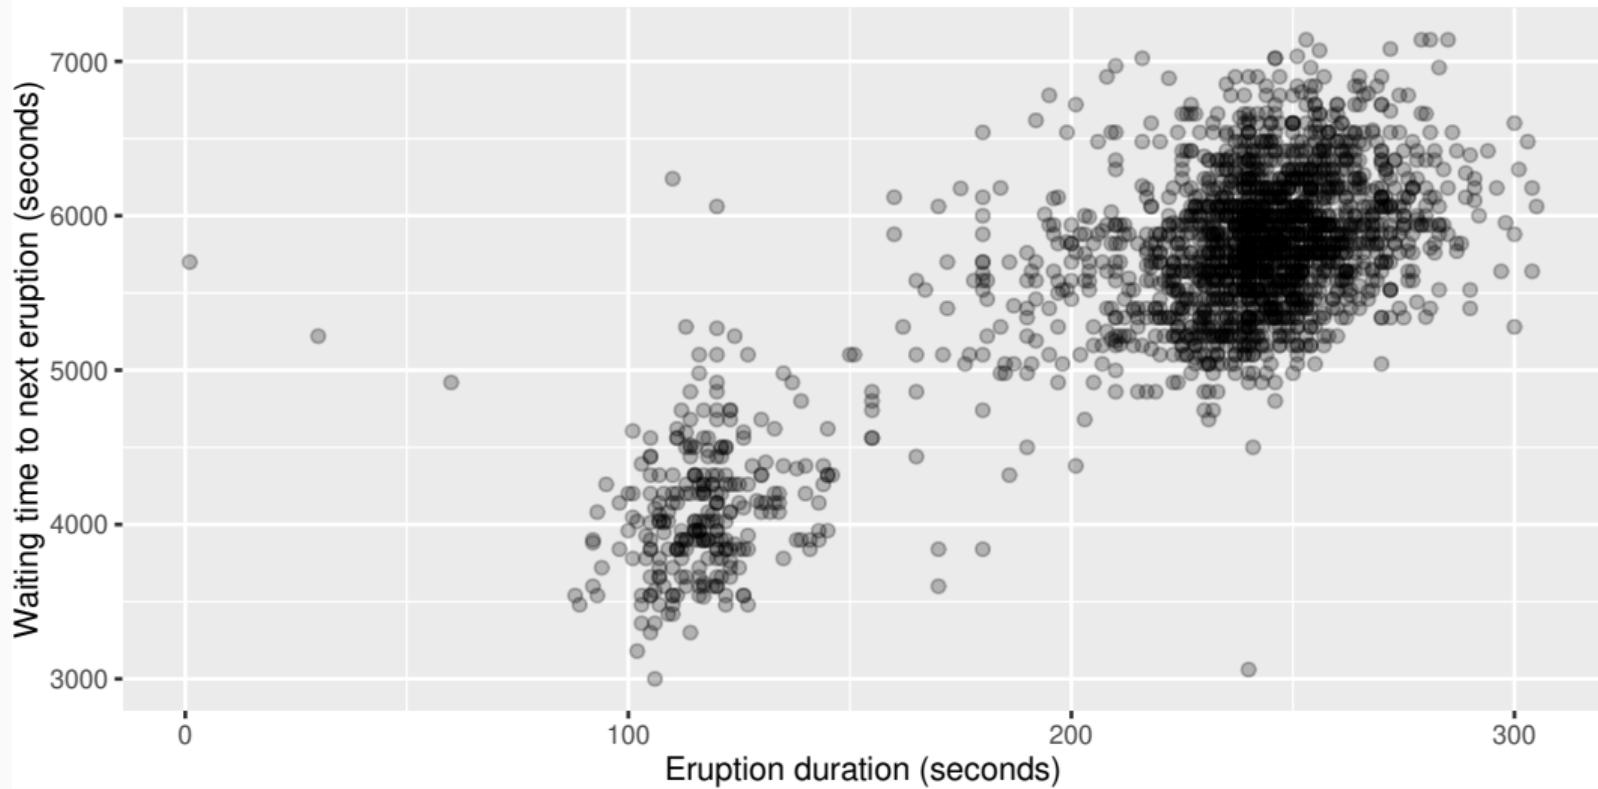

Let  $d_1 =$  smallest death time of 0-homology for Rips filtrations of  $n$  points from distribution over  $\mathbb{R}^m$ ,  $m \geq 3$ , s.t. density bounded above. Then  $nd_1 \rightarrow \infty$  as  $n \rightarrow \infty$ .

# Lookout algorithm

- 1  $\mathbf{Y}$  = data matrix with rows  $\mathbf{y}_1, \dots, \mathbf{y}_n$ .
- 2  $\hat{\Sigma}$  = orthogonalized Gnanadesikan-Kettenring estimate of  $\text{Cov}(\mathbf{Y})$ , with eigendecomposition  $\hat{\Sigma} = \mathbf{U}\mathbf{D}\mathbf{U}^\top$ .
- 3 Rotate and scale the data:  $\mathbf{Z} = \mathbf{U}\mathbf{Y}$ .
- 4 Compute persistence homology barcode of  $\mathbf{Z}$  for dim zero using Vietoris-Rips diameter; obtain ordered death diameters  $\{d_i\}_{i=1}^n$ .
- 5  $d_\gamma^* = \gamma$  sample quantile computed from  $\{d_i\}_{i=1}^n$ .
- 6 Compute kde:  $f_i = \hat{f}(\mathbf{z}_i)$ ,  $i = 1, \dots, n$ , where  $\mathbf{H} = (d_\gamma^*)^{2/m} \mathbf{I}_m$ .
- 7 Compute LOO kde values  $f_{-i} = \frac{1}{n-1} (nf_i - \mathbf{H}^{-1/2} K(\mathbf{0}))$ ,  $i = 1, \dots, n$ .
- 8 Fit GPD to largest  $1 - \beta$  of surprisals  $\{-\log f_i\}_{i=1}^n$ , constraining shape parameter to be non-positive.
- 9  $p_i = (1 - \beta)P(-\log f_{-i} | \hat{\mu}, \hat{\sigma}, \hat{\xi})$ ,  $P$  = GPD cdf.
